# **Chapter 1**

# The spatially-adaptive solution of the azimuthally Fourier-decomposed equations of 3D time-harmonic linear elasticity on unstructured meshes

In this tutorial we re-visit the solution of the time-harmonic equations of 3D linear elasticity in cylindrical polar coordinates, using a Fourier decomposition of the solution in the azimuthal direction. The driver code is very similar to the one discussed in another tutorial — the main purpose of the current tutorial is to demonstrate the use of spatial adaptivity on unstructured meshes. Compared to the test case considered in the other tutorial we study a slightly less contrived test problem: the forced time-harmonic oscillations of a finite-length, hollow cylinder, loaded by a time-periodic pressure load on its inner surface.

**Acknowledgement:** This implementation of the equations and the documentation were developed jointly with Robert Harter (Thales Underwater Systems Ltd) with financial support from a KTA Secondment grant from University of Manchester's EPSRC-funded Knowledge Transfer Account.

# 1.1 The test problem

The figure below shows the problem considered in this tutorial: an annular elastic body that occupies the region  $r_{\min} \leq r \leq r_{\max}, z_{\min} \leq z \leq z_{\max}$  is loaded by a time-harmonic pressure load acting on its inner surface (at  $r=r_{\min}$ ). The upper and lower ends of the hollow cylinder (at  $z=z_{\min}$  and  $z=z_{\min}$ ) are held at a fixed position. Here is an animation of the resulting displacement field for  $r_{\min}=0.1$  and  $r_{\max}=1.1$ .

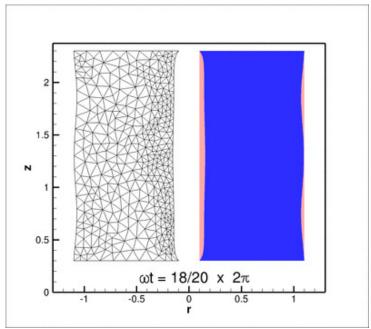

Figure 1.1 Forced oscillations of a thick-walled, hollow cylinder, subject to a pressure load on its inner surface. The pink shape in the background shows the cylinder's undeformed shape (in a radial plane); the mesh plotted in the region r < 0 illustrates how spatial adaptivity refines the mesh in regions of sharp displacement gradients (near the loaded surface and the supports).

#### 1.2 The numerical solution

The driver code for this problem is very similar to the one discussed in another tutorial. Running sdiff on the two driver codes

```
\label{lem:composed_linear} $$ \ensuremath{\mathsf{demo\_drivers/time\_harmonic\_fourier\_decomposed\_linear\_} \leftarrow $$ \ensuremath{\mathsf{elasticity/cylinder.cc}}$
```

and

```
demo_drivers/time_harmonic_fourier_decomposed_linear_←
   elasticity/cylinder/pressure_loaded_cylinder.cc
```

shows you the differences, the most important of which are:

- The change of the forcing to a spatially constant pressure load on the inside boundary.
- The provision of the actions\_before/after\_adapt() functions and a helper function complete\_\( \sim \) problem\_setup() which rebuilds the elements (by passing the problem parameters to the elements) following the unstructured mesh adaptation. (The need/rationale for such a function is discussed in another tutorial.)
- The mesh generation and the application of boundary conditions at the upper and lower boundaries of the hollow cylinder. .
  - All of this is reasonably straightforward and provides a powerful code that automatically adapts the mesh in regions of large displacement gradients. Have a look through the driver code and play with it.

## 1.3 Code listing

Here's a listing of the complete driver code:
